

# Python for Data Science Day 4

By Craig Sakuma

# Schedule - Day 4

Time	Topic
10:00 – 11:00	Review Data Cleaning and Matplotlib
11:00 – 12:00	Overview of Machine Learning
12:00 – 1:00	Lunch
1:00 – 3:30	K-Nearest Neighbors
3:30 – 3:45	Break
3:45 – 5:00	Random Forest

### What is Machine Learning?

"A field of study that gives computers the ability to learn without being explicitly programmed." (1959)

- Arthur Samuel, Al Pioneer

### **Netflix Prize**

- Challenge to make 10% improvement in Netflix's recommendation system
- Grand prize was \$1 million, with annual \$50k progress prize to the leader at the end of the year
- 50k teams participated from over 180 countries
- Ratings matrix contained over 100 million numerical entries from 500k users across 17k movies
- Competition began in 2006 and the grand prize was awarded in 2009
- Winning entry was an ensemble of 100's of models

# Supervised vs. Unsupervised

#### Supervised

- Requires truth set of data for training algorithms
- Examples:
  - Forecasting sales
  - Classifying spam

#### Unsupervised

- Autonomous algorithm that requires no training
- Examples:
  - Cluster analysis
  - Anomaly detection

### **Machine Learning Categories**

	Continuous	Categorical
Supervised	Regression	Classification
Unsupervised	Dimension Reduction	Clustering

# **Supervised Training**

- Training Set
  - Data used to create coefficients for model
  - For example, data set used to create a linear regression
- Test Set
  - Data used to measure performance of trained model

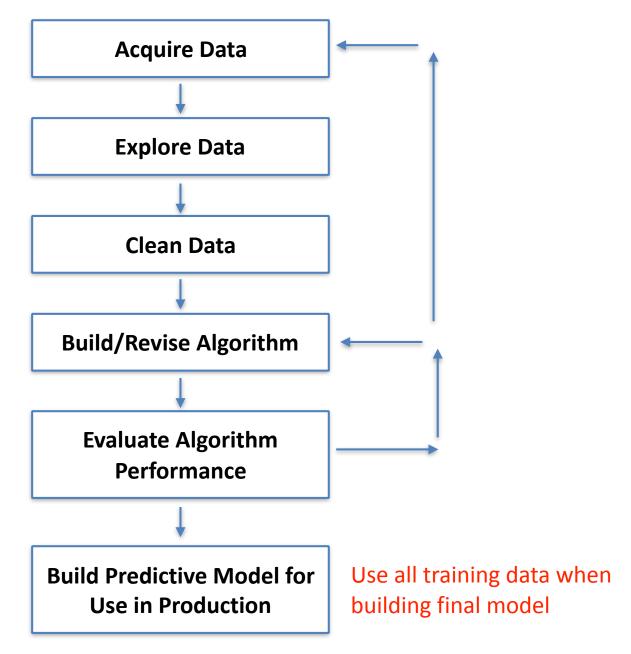

# **Training Set**

Age	Sex	Pclass	Survived?	
25	Male	3	FALSE	
17	Female	1	TRUE	Classes
40	Male	2	FALSE	(target)
9	Female	2	TRUE	

Independent Variables (features)

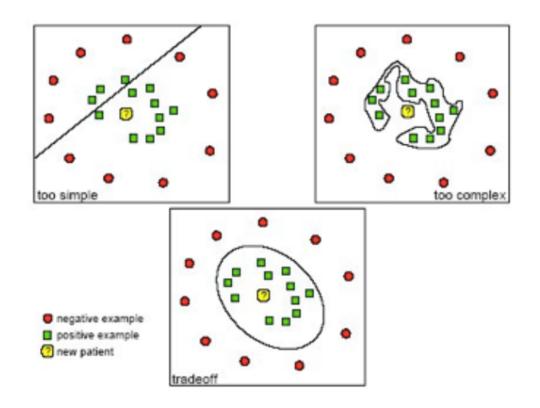

### **Data Science Process**

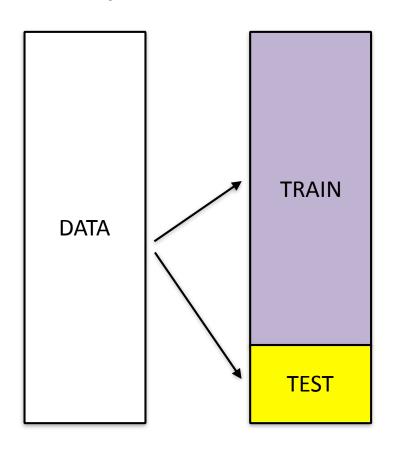

# Underfitting and Overfitting

### **Cross-validation**

#### Split Data Set

- Separate the data into two groups
- Use part of data to train the model
- Use trained model to predict out come for test data
- Compare predictions with actual results

Measure model performance on accuracy of predictions

### Iris Data Set

- Three species of iris
  - Setosa
  - Versicolour
  - Virginica
  - Species are encoded as 0,1 and 2 respectively
- Four measurements used to identify species
  - Sepal length
  - Sepal width
  - Petal length
  - Petal width

**QuantSprout** 

# Import the Iris Data Set

#### Import pandas and numpy packages

import numpy as np import pandas as pd

#### Read the iris CSV file

```
iris = pd.read_csv('iris.csv')
iris.head()
```

#### Explore the data

```
print iris.info()
print iris.describe()
```

sklearn.cross\_validation.train \_test\_split

Examples using

sklearn.cross\_validation.tra
in\_test\_split

#### sklearn.cross\_validation.train\_test\_split

sklearn.cross\_validation.train\_test\_split(\*arrays, \*\*options)

[source]

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and next(iter(ShuffleSplit(n\_samples))) and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Parameters: \*arrays : sequence of arrays or scipy.sparse matrices with same shape[0]

Python lists or tuples occurring in arrays are converted to 1D numpy arrays.

test\_size : float, int, or None (default is None)

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is automatically set to the complement of the train size. If train size is also None, test size is set to 0.25.

train\_size : float, int, or None (default is None)

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random\_state : int or RandomState

Pseudo-random number generator state used for random sampling.

Returns: splitting: list of arrays, length=2 \* len(arrays)

List containing train-test split of input array.

# Separate Features and Target

Create two variables for features and target. Convert them into values.

Scikit-learn has a function to split data into training and testing sets

from sklearn.cross\_validation import train\_test\_split

### **Train Test Split**

Apply train\_test\_split to sample data

### **Train Test Split**

View results of train\_test\_split

```
print 'Training Set'
print f_train
print t_train,'\n\n'
print 'Test Set'
print f_test
print t_test
```

# **Split Iris Data**

Split the iris data into training set and test set

```
features_train, features_test, target_train,
    target_test = train_test_split(
    iris_features, iris_target, test_size=0.20,
    random_state=0)
```

```
print features_train.shape
print features_test.shape
print target_train.shape
print target test.shape
```

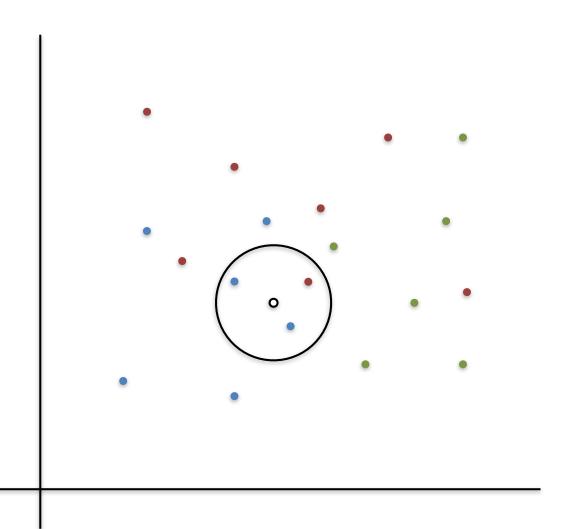

# **Classification Algorithms**

- Logistic Regression
- Naive-Bayes
- Decision Trees
- Support Vector Machines
- Neural Networks
- K-Nearest Neighbors
- Random Forest

# **K Nearest Neighbors**

Suppose you want to predict the white dot

- 1. Pick a value for k
- 2.Find colors of the k nearest neighbors
- 3.Assign the most common color

### **KNN Considerations**

- Scaling of Data has large impact on algorithm (normalization is frequently used)
- Adjust the value of k to optimize the algorithm
- Can become computationally expensive at large scale

sklearn.neighbors.KNeighbors Classifier

Examples using

sklearn.neighbors.KNeighbors Classifier

#### sklearn.neighbors.KNeighborsClassifier

class sklearn.neighbors.KNeighborsClassifier(n\_neighbors=5, weights='uniform', algorithm='auto', leaf\_size=30, p=2, metric='minkowski', metric\_params=None, \*\*kwargs) [source]

Classifier implementing the k-nearest neighbors vote.

Parameters: n\_neighbors : int, optional (default = 5)

Number of neighbors to use by default for k\_neighbors queries.

weights: str or callable

weight function used in prediction. Possible values:

- · 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance': weight points by the inverse of their distance. in this case, closer neighbors
  of a query point will have a greater influence than neighbors which are further away.
- [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

fit(X, y)

[source]

Fit the model using X as training data and y as target values

**Parameters:** X: {array-like, sparse matrix, BallTree, KDTree}

Training data. If array or matrix, shape = [n\_samples, n\_features]

**y**: {array-like, sparse matrix}

Target values of shape = [n\_samples] or [n\_samples, n\_outputs]

#### predict(X) [source]

Predict the class labels for the provided data

Parameters:	X : array of	f shape	[n_samp	les, n_	features]
-------------	--------------	---------	---------	---------	-----------

A 2-D array representing the test points.

**Returns:** y : array of shape [n\_samples] or [n\_samples, n\_outputs]

Class labels for each data sample.

$$predict_proba(X)$$
 [source]

Return probability estimates for the test data X.

Parameters:	X: array,	shape = (n_	_samples, n_	features)
-------------	-----------	-------------	--------------	-----------

A 2-D array representing the test points.

**Returns: p**: array of shape = [n\_samples, n\_classes], or a list of n\_outputs

of such arrays if n\_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

[source]

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

	, p
Parameters:	X : array-like, shape = (n_samples, n_features)
	Test samples.
	y : array-like, shape = (n_samples) or (n_samples, n_outputs)
	True labels for X.
	sample_weight : array-like, shape = [n_samples], optional
	Sample weights.
Returns:	score : float
	Mean accuracy of self.predict(X) wrt. y.

# **K-Nearest Neighbors**

Import K Nearest Neighbors from scikit-learn

from sklearn.neighbors import KNeighborsClassifier

#### Train the KNN classifier

model = KNeighborsClassifier(5).fit(features\_train, target\_train)

#### Compare predictions with actual results

print model.predict(features\_test)
print target\_test

# **K-Nearest Neighbors**

#### Predict probabilities

model.predict\_proba(features\_test)

#### Score the model

model.score(features\_test, target\_test)

### **Evaluating Algorithms**

- Model performance will vary based on how you split the data into training and testing groups
- Taking an average of the model performance across different splits improves the measurement

#### **KFold Cross-validation**

### **K-Folds Cross-validation**

sklearn.cross\_validation.KFold

Examples using
sklearn.cross\_validation.KFold

#### sklearn.cross\_validation.KFold

class sklearn.cross\_validation.KFold(n, n\_folds=3, indices=None, shuffle=False, random\_state=None) ¶

[source]

K-Folds cross validation iterator.

Provides train/test indices to split data in train test sets. Split dataset into k consecutive folds (without shuffling).

Each fold is then used a validation set once while the k - 1 remaining fold form the training set.

Parameters: n:int

Total number of elements.

n\_folds: int, default=3

Number of folds. Must be at least 2.

shuffle: boolean, optional

Whether to shuffle the data before splitting into batches.

random\_state : None, int or RandomState

Pseudo-random number generator state used for random sampling. If None, use default numpy RNG for shuffling

### **K-Folds Cross-Validation**

Import the KFold function from scikit-learn

from sklearn.cross\_validation import KFold

KFold function creates indices for separating training and test sets. Lets create indices for a data set of 3 records with 3 folds.

k\_fold\_indices = KFold(3, n\_folds=3, shuffle=False)
print k\_fold\_indices

### **K-Folds Cross-Validation**

Let's see what is in the k\_fold\_indices

```
for x,y in k_fold_indices:

print x,y
```

Remember how to index numpy arrays with indices?

```
sample = np.array([0,10,20,30,40,50])
indices = [4,0,2]
print sample[indices]
```

### **K-Folds Cross-Validation**

Let's use indices to index values in an array.

```
data = np.array(['a','b','c'])
for x,y in k_fold_indices:
    print data[x], data[y]
```

### **Cross-Validation Function**

Inputs to function include data, classifier function, number of folds and random state

### **Cross-Validation Function**

Create sets of indices for separating data into training and test sets. There will be k sets of indices

## **Cross-Validation Function**

Iterate through the sets of indices to train and score each scenario

```
for train_indices, test_indices in k_fold_indices:
```

## **Use Cross-Validation Function**

Test the function with different numbers of neighbors

## **Exercise**

- Load the clean\_data.csv file as DataFrame
- Separate the data into features (age, sex, pclass dummies) and target (survived) and convert to numpy array
- Evaluate KNN model using cross-validation function
- Bonus: Try different numbers of neighbors using a for loop

## **Data Normalization**

- Technique for adjusting the scale of data
- Calculate mean and standard deviation of all samples for each variable
- Subtract the mean and divide by the standard deviation

## **Data Normalization**

Calculate the mean and standard deviation

```
avg_age = data.Age.mean()
stdev_age = data.Age.std()
```

Subtract the mean and divide by the standard deviation

```
data['Age_norm'] = (
          data.Age - avg_age) / stdev_age
```

## **Data Normalization**

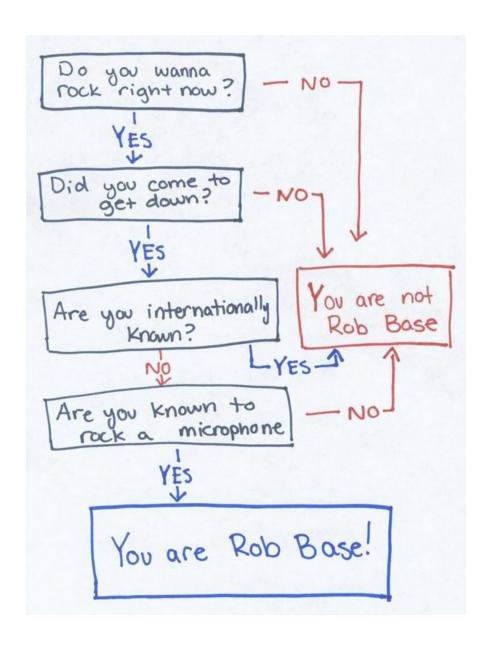

### Create new features using normalized data

```
features_norm = data[['Age_norm', 'Sex', 'Pclass_1', 'Pclass_2', 'Pclass_3']].values
```

#### Test KNN on normalized data

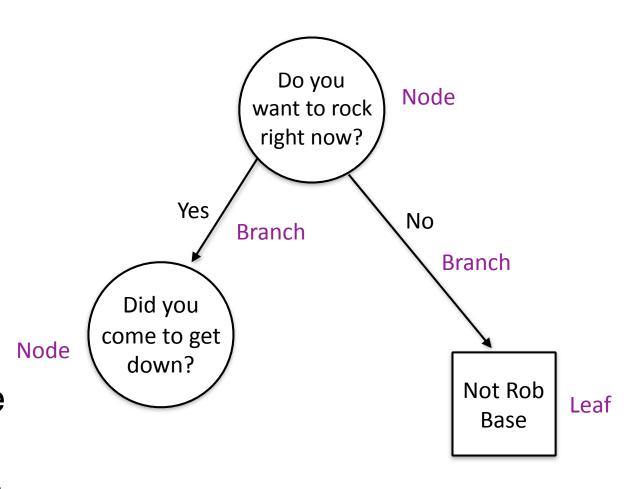

## Is This a Decision Tree?

## **Decision Trees**

- Trees consist of:
  - Nodes (questions)
  - Branches (answers)
  - Leaves (end points)
- Acyclic flows in one direction
- No split is necessary when all records are from same class

### **Decision Trees**

- Algorithm selects optimal node that creates the largest increase in purity
- Decision trees are susceptible to overfitting
- Techniques for preventing overfitting
  - Minimum number of records for leaf
  - Maximum depth for branches
- One technique is to purposely overfit, but manually prune branches

### **Random Forest**

- Ensemble algorithm (mix of many models)
- Collection of decision trees
- Evaluates predictions from many models and selects the most common classification
- Features are randomly selected for each decision tree
- Bagging (Bootstrap Aggregating) is also applied to each tree
  - Sample of the data set is used for training
  - Samples are drawn with replacement

## Why Random Forest Is Popular?

- Add all your data and algorithm will prioritize
- Not susceptible to overfitting
- Doesn't require normalization
- Solid performance in wide range of applications

#### 3.2.4.3.1. sklearn.ensemble.RandomForestClassifier

class sklearn.ensemble.RandomForestClassifier(n\_estimators=10, criterion='gini', max\_depth=None, min\_samples\_split=2, min\_samples\_leaf=1, min\_weight\_fraction\_leaf=0.0, max\_features='auto', max\_leaf\_nodes=None, bootstrap=True, oob\_score=False, n\_jobs=1, random\_state=None, verbose=0, warm\_start=False, class\_weight=None) { [source]

A random forest classifier.

A random forest is a meta estimator that fits a number of decision tree classifiers on various sub-samples of the dataset and use averaging to improve the predictive accuracy and control over-fitting.

Parameters: n\_estimators : integer, optional (default=10)

The number of trees in the forest.

criterion: string, optional (default="gini")

The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "entropy" for the information gain. Note: this parameter is tree-specific.

max\_features : int, float, string or None, optional (default="auto")

### **Random Forest**

#### Import the Random Forest function

from sklearn.ensemble import RandomForestClassifier

#### Create an instance of the model

model = RandomForestClassifier(random\_state=0)

### **Random Forest**

Run the cross-validation function using the Random Forest algorithm

cross validate(features, target, model, 10, 0)

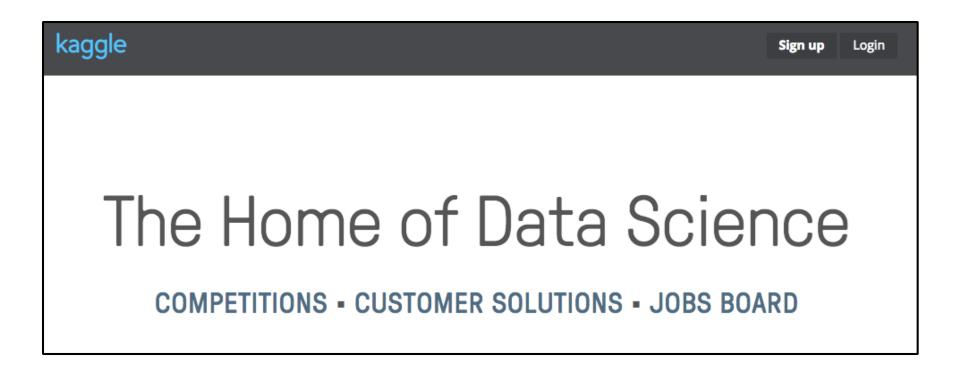

Investigate feature importances

print model.fit(features, target).feature\_importances\_

# Kaggle

Data prediction competitions

## Kaggle

- Create an account
- Find "Titanic: Machine Learning from Disaster"
- Submission Instructions:

"You should submit a csv file with exactly 418 entries plus a header row. This must have exactly 2 columns: PassengerId (which can be sorted in any order), and Survived which contains your binary predictions: 1 for survived, 0 for did not."

### **Make Predictions**

- Train your machine learning algorithm with training data
- Read the test.csv file
- Clean test data
- Predict outcomes for test data
- Convert predictions into a DataFrame
- Save DataFrame as a CSV file (remember to exclude the index)
- Submit predictions to Kaggle site

## **Train Model on All Data**

Train the model using the best data available

```
model = RandomForestClassifier(
    random state=0).fit(features,target)
```

## Read test.csv Data

Make sure you investigate the data

```
test_data = pd.read_csv('test.csv')
print test_data.head()
print test_data.info()
print test_data.describe()
```

## Clean and Prep the Data

#### Clean text and missing values

### Convert Pclass to dummies and merge to data

## Clean and Prep the Data

Select features from test data and convert to numpy array

```
test_features = test_data[['Age', 'Sex', 'Pclass_1', 'Pclass 2', 'Pclass 3']].values
```

## **Make Predictions**

#### **Create Predictions**

predictions = model.predict(test\_features)

#### Add Predictions as new column in DataFrame

test\_data['Survived'] = predictions

### Save as CSV (make sure you set index=False)

## What We've Accomplished

- Built foundation of Python skills
- Acquired and stored data in variety of formats (e.g., csv, Excel, SQL, JSON)
- Used API to request data
- Explored, cleaned and summarized data
- Created data visualizations
- Implemented machine learning algorithms

## **Next Steps**

- Practice, Practice
  - Find a fun project
  - Lots of public data sets and web data to scrape
  - Pair programming buddy
- Join a Python Meetup
  - San Francisco Python recommend
     Project Night event
  - Bay Area Python Interest Group (BayPIGgies)

## **Next Steps**

- Keep Learning
  - Pycon and Pydata videos on YouTube
  - Python for Data Analysis (O'Reilly)
  - Machine Learning Classes (Coursera, Edx)
  - datasciencemasters.org
  - Kaggle competitions
- Don't Be Afraid to Ask for Help
- Keep in Touch

yelp.com/biz/quantsprout-san-francisco
